

AI Automation for a Business Analysis Team

Practical examples of automating internal processes on an OSS/BSS project
Sparx EA, Confluence, Jira, and a low-code platform · February - June 2026

Business Analysis Team Lead with Hands-on AI Automation Experience

Expertise

System and business analysis for telecom OSS/BSS solutions, covering the end-to-end order journey across multiple systems, from order capture to technical service activation. Led a team of up to six business analysts.

Automation

From February to June 2026, created tools to automate my team's work. Designed the architecture and logic, defined implementation requirements, and reviewed the final results. Code was developed with Claude Code and validated with OpenAI Codex.

Result

Fewer repetitive tasks and errors, more time for analysis, and clearer visibility into workload and progress.

Tools Delivered in Weeks, Not Months

Estimated manual effort reduction: 20 to 150+ hours per use case

1 Situation

Preparing documentation involved repetitive manual work: exporting data, redrawing diagrams, reconciling information, and compiling status updates.

2 Problem

For narrow use cases, conventional automation was not cost-effective: it required integrations, approvals, and months of development. As a result, repetitive operations continued to be performed manually.

3 Solution

Purpose-built tools were created for specific manual operations and integrated with Jira, Confluence, Sparx EA, and the low-code platform. AI agents accelerated implementation of business logic and integrations.

Tool Examples

Use Case	Manual Effort Reduction	Tool
Exporting solution design from a low-code configuration server and reconciling discrepancies	80-120 hrs per release Estimated	CHROME EXTENSION
Migrating solution design from Sparx Enterprise Architect to Confluence, including redrawing diagrams in draw.io	150+ hrs Estimated	CHROME EXTENSION
Tracking approximately 200 customer comments on solution design	25-30 hrs	DASHBOARD
Tracking the analysis of approximately 150 change requests in Jira	~20 hrs	DASHBOARD
Delivery reporting beyond standard Jira views	Reduced from 3 days to 4 hrs	EXCEL REPORTS
Translating configuration language expressions into plain language	Not quantified	AGENTIC WORKFLOW MVP

Updating Solution Design on the Low-Code Platform and Exporting It to Confluence

Challenge

Solution design was maintained on a low-code configuration server, but the built-in export did not work. For more than a year, documentation had been prepared manually and gradually drifted from the actual configuration.

Solution

The first tool compared Confluence documentation with objects on the low-code platform and highlighted discrepancies. After an analyst approved the changes, the tool automatically updated the corresponding object descriptions. Once developers configured the export templates, a second tool transferred documentation from the internal Confluence instance to the external one.

Outcome

Both workflows were implemented and tested: updating object descriptions on the low-code platform and transferring documentation to the external Confluence instance.

80-120

hours of manual work saved per release

Estimated

Migrating Solution Design from Sparx Enterprise Architect to Confluence

Challenge

Solution design was stored in Sparx Enterprise Architect, which no longer met the needs of developers and testers. Migrating it to Confluence required diagrams to be redrawn manually and notes, linked documents, and complex tables with merged cells to be converted.

Solution

The tool converts diagrams into editable draw.io format, transfers notes, linked documents, and tables with merged cells, and generates ready-to-use Confluence pages.

Outcome

The tool was handed over to analysts for day-to-day use and to engineers for support and further development.

150+

hours of manual migration and formatting

Estimated

Four More Tools for Managing Work and Automating Repetitive Tasks

25-30 hrs

Customer Comments

Around 200 comments across 40 pages over three weeks. The dashboard consolidated statuses, showed how comments were distributed across analysts, and supported planning of the remaining work.

DASHBOARD

~20 hrs

Change Requests

Around 150 requests, each requiring about eight minutes of repetitive manual processing. The tool added the analysis outcome, labels, and a comment directly in Jira.

DASHBOARD

3 days → 4 hrs

Delivery Reports

The report covered statuses, schedule changes and their reasons, and blockers. It was produced in four hours instead of three days of manual work.

EXCEL REPORTS

MVP

Configuration Language

The MVP translated expressions from the low-code platform's configuration language into plain language. The project was closed before rollout.

AGENTIC WORKFLOW

Principles for Developing Automation Tools

01

Use Case Selection

Priority is given to simple, repetitive tasks carried out by many people.

02

Algorithm First

Clear rules are implemented as algorithms. An AI model is used only where interpretation is required.

03

Data Stays Inside

Customer data is not sent to external AI services. Only code, not customer data, is used during development.

04

Cross-Validation

Code generated with Claude Code is checked with OpenAI Codex and then reviewed manually.

05

No Additional Access

Tools operate only with the access rights already assigned to the user.

06

Ownership and Evolution

Each tool and shared skill has a designated owner. Any team member can propose changes through Git. The owner reviews and approves changes. Shared skills are managed separately from tool code.

Personal Project: Telegram Assistant with an Open Architecture

What It Is

An agentic system in Telegram for managing tasks and reminders, monitoring email, and tracking habits.

Changes via Chat

The same Telegram chat can be used to request changes to the assistant itself. Claude Code turns the request into a code change, applies it, and restarts the assistant. The new capability becomes available in the chat immediately.

Architecture

The assistant is deployed on a VPS and uses the Anthropic API. Agents are separated by role and permissions, secrets are stored in a secrets manager, and data is kept in an encrypted SQLite database. Irreversible actions require explicit confirmation in Telegram.
